

# Illustrated companion for Folland's “The Baire Category Theorem and its Consequences”

Riley Quinn Levy  December 23, 2019

These notes are a companion for Section 5.3: “The Baire Category Theorem and its Consequences”, in Folland’s *Real Analysis: Modern Techniques and their Applications*.

Definition 1 (nowhere dense) A nowhere dense set’s closure has empty interior.[2]

Definition 2 (meager) A meager set is countable union of [nowhere dense](#) sets. [3, pg. 161]

Theorem 3 (Baire category) If  $X$  is a completely metrizable space,

1. countable intersections of open dense subsets are dense,
2.  $X$  is not [meager](#). [3, pg. 161]

Proof.

1. Consider  $U_i$ , a sequence of dense open sets. It suffices to show a nonempty open set  $W$  meets  $\bigcap U_i$ . The proof proceeds by inductively<sup>1</sup> nesting open balls inside successive  $W \cap U_i$ . By assumption of density,  $W \cap U_1$  is nonempty. It is also open, so there is some  $B_1 = B(x_1, r_1)$  with  $\overline{B_1} \subseteq W \cap U_1$ . Observe  $B_1 \cap U_1$  is also open; therefore, find a  $B_2 = B(x_2, r_2)$  where  $\overline{B_2} \subseteq B_1 \cap U_1$  and proceed inductively:  $B_{n+1} = B(x_n, r_n)$  where  $\overline{B_{n+1}} \subseteq B_n \cap U_n$ . These are nested and

$$x_n \in \underbrace{B_n}_{\subseteq U_n} \subseteq \underbrace{B_{n-1}}_{\subseteq U_{n-1}} \subseteq \cdots \subseteq \underbrace{B_2}_{\subseteq U_2} \subseteq \underbrace{B_1}_{\subseteq U_1} \subseteq W$$

<sup>1</sup>In a general (nonseparable) metric space, this requires the axiom of dependent choice. In ZF, [theorem 3 \(Baire category\)](#) and the axiom of dependent choice are equivalent.[1]

If  $r_n$  are selected such that  $r_n \rightarrow 0$ —e.g., by requiring  $r_n < 2^{-n}$  at each step of the induction—then  $x_n$  is Cauchy. By completeness, there is a limit; call it  $x$ . But because  $x_i$  is eventually in  $B_n$ ,  $x \in \overline{B(x_n, r_n)} \subseteq B(x_{n-1}, r_{n-1})$  for all  $n$ . Then

$$x \in \dots \underbrace{B_n}_{\subseteq U_n} \subseteq \underbrace{B_{n-1}}_{\subseteq U_{n-1}} \subseteq \dots \subseteq \underbrace{B_2}_{\subseteq U_2} \subseteq \underbrace{B_1}_{\subseteq U_1} \subseteq W;$$

therefore,  $x$  is in the intersection  $\bigcap U_n \cap W$ , proving it's nonempty.

2. By the previous result, it suffices to show the complement of any **nowhere dense** set contains an dense open set. Suppose  $N$  is nowhere dense. Then  $N^c$  is dense; hence,  $(N^c)^o$  is open and dense.  $\square$

The proofs of [theorem 4 \(open mapping\)](#) and [theorem 7 \(uniform boundedness principle\)](#) both share a technique: find a bound around an arbitrary point (given by a density argument) and then translate this to a bound around the origin (via the triangle inequality and linearity).

**Theorem 4 (open mapping)** *Surjective Banach-morphisms are open.* [[3](#), pg. 162]

**Proof.** Call the morphism  $T : X \rightarrow Y$ . Let  $B_r = B(0, r) \in X$ . Because linear maps commute with translations and dilations, it suffices to show that  $0$  is an interior point of  $T(B_1)$ .

By surjectivity,  $Y = \bigcup_{n=1}^{\infty} TB_n$ . The map  $n \mapsto (Y, TB_1) \rightarrow (Y, TB_n)$  is a homeomorphism for  $n > 0$ . Therefore,  $B_1$  cannot be **nowhere dense**: if it were,  $B_n$  would be too, making  $Y$  **meager**, contradicting [theorem 3 \(Baire category\)](#).

The closure  $\overline{TB_1}$  contains an interior point  $y_0$ . For some  $r$ ,  $B(y_0, 4r) \subseteq \overline{TB_1}$ . Then there is some  $y_1 = Tx_1 \in TB_1$  within  $2r$  of  $y_0$ . In particular, its neighborhood  $B(y_1, 2r) \subseteq B(y_0, 4r) \subseteq \overline{TB_1}$ . We translate this to an inclusion of points around the origin as follows.

If  $\|y\| < 2r$ , then  $y_1 - y \in \overline{TB_1}$  so

$$y = y_1 - (y_1 - y) = Tx_1 - (y_1 - y) \in \overline{T(x + B_1)} \subseteq \overline{TB_2}.$$

Halving this shows  $\|y\| < r \implies y \in \overline{TB_1}$ ; repeatedly halving shows

$$\|y\| < r2^{-n} \implies y \in \overline{TB_{2^{-n}}}. \quad (1)$$

Now, chase an arbitrary  $y$  in  $\{y : \|y\| < r/2\}$  with a sequence of  $Tx_i$ . Equation (1) guarantees an  $x_1 \in B_1$  such that  $\|y - Tx_1\| < r/4$ , and, by induction, a sequence such that  $\|y - \sum_1^n Tx_i\| < r2^{n-1}$  with  $x_i \in B_i$ . The series  $\sum x_i$  is hence absolutely convergent; by completeness, it has some limit  $x$ . But

$$\|x\| \leq \sum_i \|x_i\| = \sum_i 2^{-i} = 1$$

with  $Tx = \lim T(\sum x_i) = y$  by construction. Therefore  $y \in TB_1$  itself, not just its closure. Conclude

$$\underbrace{\{y : \|y\| < r/2\}}_{\text{open nhod of } 0} \subseteq TB_1. \quad \square$$

Because the inverse of an open map is continuous,

Corollary 5 (bounded inverse) *A bijective Banach-morphism is an isomorphism. [3, pg. 162]*

Theorem 6 (closed graph) *A linear map between Banach spaces is continuous iff its graph is closed. [3, pg. 163]*

Proof. Let  $T : X \rightarrow Y$ . Denote its graph by  $\Gamma := \{(x, Tx) : x \in X\}$ . Let  $\pi_X, \pi_Y$  indicate the projection maps from  $\Gamma$  to  $X$  and  $Y$  respectively.

Suppose  $T$  is continuous. Suppose  $(x_n, Tx_n)$  is a convergent sequence in  $\Gamma$ . Then there is some  $x = \lim x_n$ . But by continuity,  $Tx_n \rightarrow Tx$  hence  $(x_n, Tx_n) \rightarrow (x, Tx) \in \Gamma$ , so  $\Gamma$  is closed.

Suppose  $\Gamma$  is closed. Then, as  $X \times Y$  is complete, being a closed subset,  $\Gamma$  is complete as well. Then  $\pi_X$  is a bijective Banach-morphism so it is actually an isomorphism by corollary 5 (bounded inverse). Hence  $T = \pi_Y \circ \pi_X^{-1} : X \rightarrow Y$  is a continuous.  $\square$

Theorem 7 (uniform boundedness principle)

1. If  $\sup_{T \in A} \|Tx\| < \infty$  for all  $x$  in a nonmeager subset of  $X$ , then  $\sup_{T \in A} \|T\| < \infty$ .
2. If  $X$  is a Banach space and  $\sup_{T \in A} \|Tx\| < \infty$  for all  $x \in X$ , then  $\sup_{T \in A} \|T\| < \infty$ . [3, pg. 163]

Proof. By theorem 3 (Baire category), a Banach space is nonmeager, hence (2) follows from (1). So it suffices to prove (1).

Let

$$E_n := \left\{ x \in X : \sup_{T \in A} \|Tx\| \leq n \right\} = \bigcap_{T \in A} \{x \in X : \|Tx\| \leq n\}.$$

The  $E_n$  are closed. By hypothesis of (1), some  $E_n$  is nonmeager; therefore it contains a nontrivial closed ball  $B(r, x_0)$ . Now, we use this fact to construct a ball around 0 contained in  $E_{2n}$ . If  $\|x\| \leq r$  then  $x_0 - x \in E_n$ :

hence

$$\|Tx\| \leq \|T(x - x_0)\| + \|Tx_0\| = \|T(x_0 - x)\| + \|Tx_0\| \leq 2n.$$

Therefore,  $\|Tx\| \leq 2n$  whenever  $T \in A$  and  $\|x\| \leq r$ . Therefore  $\sup_{T \in A} \|T\| \leq 2n/r$ .  $\square$
